Well, here I take into consideration that you have an elementary idea of phasors. In DC circuits with resistors, you sum up the voltage drops, which equals the source voltage. But here, since we are dealing with AC, we have to consider the vector sum of the R, L and C voltages. This will definitely equal the source voltage, if done correctly.

A good guideline is never to apply more than 80% of the nominal voltage of the capacitor. This means that A 50V capacitor should never have more than 40V applied to it. A 63V capacitor should never have more than 50V applied to it. A 80V capacitor should never have more than 63V applied to it.

Calculate the voltage across a capacitor with a stored charge of 0.002 coulombs and a capacitance of 0.0001 farads: Given: $Q (C) = 0.002C$, $C (F) = 0.0001F$. Capacitor voltage, $V_c(V) = Q (C) / C (F)$ $V_c(V) = 0.002 / 0.0001$. $V_c(V) = 20V$. Determine the voltage across a capacitor that stores a charge of 0.005 coulombs and has a capacitor voltage ...

Capacitors with different physical characteristics (such as shape and size of their plates) store different amounts of charge for the same applied voltage V across their plates. The capacitance C of a capacitor is defined as the ratio of the maximum charge Q that can be stored in a capacitor to the applied voltage V across its plates. In other words, capacitance is the largest amount of ...

Capacitors in Parallel. Figure 19.20(a) shows a parallel connection of three capacitors with a voltage applied. Here the total capacitance is easier to find than in the series case. To find the equivalent total capacitance C_p , we first note that the voltage across each capacitor is V , the same as that of the source,

Replacing a capacitor with something that has a higher voltage rating is always safe. The only problem there is that a capacitor rated for a higher voltage is often physically larger, everything else being equal. Make sure they actually fit in the same space. Sometimes it is also safe to use capacitors with a larger capacitance (Farads).

Otherwise, the capacitor loses much of its capacitance due to dc bias or temperature. The value can be increased if the input voltage is noisy. 7 Output Capacitor Selection The best practice is to use low-ESR capacitors to minimize the ripple on the output voltage. Ceramic capacitors are a good choice if the dielectric material is X5R or better.

Here is my analysis. Experiments performed by UL in the course of analysis of silver PCB surface finish, demonstrated that the withstand voltage of a pair of parallel conductors is purely a function of the spacing rather than surface finish. Based on the experiments, UL specified withstand voltage of 40 volts/mil or about 1.6 kV/mm in their UL796 Standard for Printed Wiring Boards.
