Instead of thinking of capacitors in terms of charged plates, I like to think of them as devices that build up voltage as charge is pushed through them. When capacitors are connected in series, the total capacitance is less than any one of the series capacitors' individual capacitances. If two or more capacitors are connected in series, the overall effect is that of a single (equivalent) capacitor having the sum total of the plate spacings of the individual capacitors. As we've just seen ...

Well, maybe people rarely see this configuration; however, this trick could be used to create high-voltage bipolar capacitors. If you series-connect two equal value capacitors in series, cathode-to-cathode and use only the positive lead of each cap to connect to other part of the circuits. This trick are very often seen in audio equipments.

**Capacitors in Parallel.** Figure 19.20(a) shows a parallel connection of three capacitors with a voltage applied. Here the total capacitance is easier to find than in the series case. To find the equivalent total capacitance  $C_p$ , we first note that the voltage across each capacitor is  $V$ , the same as that of the source, since they are connected directly to it through a conductor.
