Lithium metal has become one of the most attractive anodes for rechargeable batteries due to its enormous theoretical capacity of up to 3 860 mAh g<sup>-1</sup> and extremely low reduction potential (- 3.04 V) [1,2,3,4,5]. Since the commercialization of LIBs in the 1990s, their applications have expanded from mobile electronic devices to electric vehicles and stationary ...

The movement of the lithium ions creates free electrons in the anode which creates a charge at the positive current collector. The electrical current then flows from the current collector through a device being powered (cell phone, computer, etc.) to the negative current collector. The separator blocks the flow of electrons inside the battery.

In order to protect the battery cell, it is not recommended to charge the lithium battery with a high current. If the battery is charged with a low current and a large current, it will heat up quickly and damage the battery. If
