In this case, we have a 12 V battery connected in parallel with a 12 mF capacitor and a 4 mF capacitor. To find the total charge, we can use the equation Q = CV, where Q is the charge, C is the capacitance, and V is the voltage. Thus: For the 12 mF capacitor: Q1 = 12 mF × 12 V = 144 mC; For the 4 mF capacitor: Q2 = 4 mF × 12 V = 48 mC

RC Circuits. An (RC) circuit is one containing a resisto r (R) and capacitor (C). The capacitor is an electrical component that stores electric charge. Figure shows a simple (RC) circuit that employs a DC (direct current) voltage source. The capacitor is initially uncharged. As soon as the switch is closed, current flows to and from the initially uncharged capacitor.

The polarity of a battery or capacitor determines the direction that electricity flows. For batteries, there are two polarities: positive and negative. This means that electricity can flow in either direction through a battery. Capacitors have only one polarity, which means that electricity can only flow in one direction through a capacitor.
