Introduction to Electromotive Force. Voltage has many sources, a few of which are shown in Figure (PageIndex{2}). All such devices create a potential difference and can supply current if connected to a circuit. A special type of potential difference is known as electromotive force (emf). If the electromotive force is not a force at all, then what is the emf and what is a source of emf? To answer these questions, consider a simple circuit of a 12-V lamp attached to a 12-V battery, as shown in Figure 10.3. The battery can be modeled as a two-terminal device that keeps one terminal at a higher electric potential than the second terminal.

Now, the equivalent resistance of the circuit is. R eq = nr + R. The current flowing through the load will be I = E eq /R eq. I = nE/(R+nr) Case 1: If nr << R then I = nE/R. If the value of the internal resistance is much lesser than the external resistance, then the current in the circuit will be n times the circuit current due to the ...

Solution: (i) There are four paths through the circuit. The potential difference across each path is 5 V. This will be equal to the EMF of each cell.

Question: (a) Describe two ways in which a battery and fuel cell are similar.Both use ---(acid-base, oxidation and reduction precipitation)--- reactions to generate an electric potential difference between two half-cells strong enough to drive a current through an external circuit. Both have an internal bridge that allows certain ---(atoms ...

A battery is a device that stores chemical energy and converts it to electrical energy. The chemical reactions in a battery involve the flow of electrons from one material (electrode) to another, through an external circuit. The flow of electrons provides an electric current that can be used to do work.

To accept and release energy, a battery is coupled to an external circuit. Electrons move through the circuit,

while simultaneously ions (atoms or molecules with an electric charge) move through the electrolyte. In a rechargeable battery, electrons and ions can move either direction through the circuit and electrolyte.

However, research on arcs in BESSs is still in its infancy. In Refs. [20, 21], a detailed study was conducted on arc fault problems triggered by the current interrupt device (CID) in 18650 lithium-ion batteries (LIBs). These studies indicate that at the moment the CID disconnects, even a voltage as low as 19 V can initiate an arc, while 35 V can sustain it.

If the external resistance is (R) and the internal resistance is (r), the total resistance of the circuit is (R + r), so that the current that flows is E(/(R + r)). Whenever a current is taken from a cell (or battery) the potential difference across its poles drops to a value less than its EMF. We can think of a cell as an EMF in series ...

Comparison of nail penetration and external short circuit. Both internal and external short circuit scenarios can result in excessive discharge rates of the energy stored in the cell resulting in heat generation. In both cases the initial response depends on the shorting current, which is determined by the resistance of its path (shorting ...

Therefore the voltmeter reads the emf of the battery when the switch is open: [mathcal E = 6.09Vnonumber] When the circuit is closed, the ammeter reads a current of (1.44A) passing through the resistor, and since the ammeter is in series with the battery, this is the current flowing through the battery's internal resistance.

Kriston et al. divided the battery short-circuit current into 3 stages. The current changes in each stage were primarily influenced by the double and diffusion layer discharge, mass transport and electromotive force respectively, suggesting that the external/internal resistance ratio was the main factor affecting current and hazard [17].

This drop is due to the battery's internal resistance. Quote: "The internal resistance of a battery is like the resistance of a water pipe. The larger the pipe (or lower the resistance), the more water (or current) can flow through it." - Dr. John Smith, Battery Expert. Calculating Internal Resistance

Explain why there is a difference between the emf and terminal voltage of a battery if the load (external resistance in the circuit) is comparable in size to the battery's internal resistance. The emf of a battery is essentially constant because it only depends on the chemical reaction (that converts chemical energy into electrical energy) going ...
