As long as the PSU cable is plugged into the computer, power gets supplied to the BIOS. However, when the cable is removed, power to the BIOS gets from the CMOS battery on the motherboard. If this battery runs out completely, the information stored in the BIOS will be lost, so it is desirable to replace it regularly before that happens.

Figure 6: NVRAM. The NVRAM may be directly soldered to the motherboard instead of being held on to it through a socket. In this case, you will have to de-solder the old circuit and solder the new one.

I also recommend that you note the battery's orientation to remember how to put the new one back in. Finally, not all motherboards use a CR2023 CMOS battery. If you're using a motherboard made for a special requirement or one that is rather small in size, the manufacturer might use another kind of battery.

Since many people don't leave their computers on 24/7, manufacturers put a coin battery on the motherboard to ensure the settings wouldn't be lost in case of power loss. Fast forward to modern times, it turns out that motherboard manufacturers don't use CMOS for BIOS settings anymore partly because those old CMOS chips only held 128 bytes.
