The voltage across the (ideal) battery is independent of the current through. That is to say, the battery is not an ohmic device and thus, does not "obey" Ohm's law. In other words, the voltage across the (non-zero) resistance is fixed by the battery; that voltage is given and is independent of Ohm's law.

The open circuit voltage of the battery can also be measured and the voltage drop (under load) can hence be calculated. Dividing this voltage drop by circuit current yields internal resistance. A note on the load resistor value of 30.5 ohms is that it was probably carefully chosen as being representative of a "mid-range" AA battery load.

On the other hand, if the resistor value are too high the current will be too low for the ADC to measure the voltage accurately. Let's do an example with typical resistor values. Then We can no longer ignore R_s in the current equation. Let's take the extreme case that R_L is much smaller than R_s . Then we can ignore R_L in the current equation, and we get $I = \frac{V_o}{R_s}$ This is the maximum current that the battery can supply (we essentially short the terminals of the battery together). This is because R_s is ...

When measuring the EMF of a battery and connecting the battery directly to a standard voltmeter, as shown in, the actual quantity measured is the terminal voltage V . Voltage is related to the EMF of the battery by $V = \text{emf} - Ir$, where I is the current that flows and r is the internal resistance of the battery.

Thus, for example, current is cut in half if resistance doubles. Combining the relationships of current to voltage and current to resistance gives $I = \frac{V}{R}$. This relationship is also called Ohm's law. Ohm's law in this form really defines resistance for certain materials.

The voltage of a car battery is a measurement of the electrical potential difference between the positive and negative terminals of the battery. A fully charged car battery typically measures around 12.6 volts, with a normal voltage range of 12.4 to 12.7 volts.. It is important to note that the voltage of a car battery can vary depending on several factors.

This means you can keep the red probe in the same port to measure current, voltage, or resistance. However, if you suspect that your circuit will be using close to or more than 200mA, switch your probe to the 10A side, just to be safe. Overloading the current can result in a blown fuse rather than just an overload display. More on that in a bit.
