The discharge voltage for the capacitor is given by: $V_o(t) = V_e + RC \frac{dV_o}{dt}$ $V_e = 0.37$ Time $T = 26.314151$ Figure 4: A capacitor voltage discharging thru resistor R . Note that for discharging case, the capacitor voltage or output reaches to 37% of initial value or $0.37 \cdot V$ at $t = \tau$.

In electrical engineering, a capacitor is a device that stores electrical energy by accumulating electric charges on two closely spaced surfaces that are insulated from each other. The capacitor was originally known as the condenser, [1] a ...

This circuit uses two 470uF electrolytic capacitors in parallel to increase the capacitance. By connecting multiple capacitors in parallel, we can get an equivalent capacitor with a larger capacity. This is done to extend the time the LED light stays on, making it easier to observe the charging and discharging process of the capacitors.

Modular multilevel converters (MMC) have the characteristics of high modularity, good availability and high-power quality. Thus, they are widely used in medium and high-power applications. To meet large capacity application requirements, a large number of capacitors is applied in parallel and series. However, capacitors are one of the most vulnerable components ...
