When you reduce the potential difference between the plates of an isolated capacitor, it is accompanied by a reduction in the charge on each plate such that the ratio $\frac{Q}{\Delta V}$ remains constant. The capacitance is hence unaffected by the reduced potential, which shows that capacitance is independent of the charge and the potential ...

A voltmeter connected across the capacitor will show a steady increase of potential difference as the charge pump operates. The capacitance is easily determined by applying the charge pump to the capacitor of interest and measuring the time required for the potential difference to reach some final value V.

By definition, a 1.0-F capacitor is able to store 1.0 C of charge (a very large amount of charge) when the potential difference between its plates is only 1.0 V. One farad is therefore a very large capacitance.

The capacitor is a component which has the ability or "capacity" to store energy in the form of an electrical charge producing a potential difference (Static Voltage) across its plates, much like a small rechargeable battery.

When the capacitor has been allowed to charge a long time, it will become "full," meaning that the potential difference created by the accrued charge balances the applied potential. In this case, the first and third terms of the Kirchhoff loop equation for the outer loop cancel, which means that no current passes through resistor (R_2).

When the key is pressed, the capacitor begins to store charge. If at any time during charging, I is the current through the circuit and Q is the charge on the capacitor, then. The potential difference across resistor = IR , and. The potential difference between the plates of the capacitor = Q/C . Since the sum of both these potentials is equal to \mathcal{E} ,

The charge Q on the capacitor is directly proportional to its potential difference V ; The graph of charge against potential difference is therefore a straight line graph through the origin; The electric potential energy stored in the capacitor can be determined from the area under the potential-charge graph which is equal to the area of a right-angled triangle:
