As almost always, the positive charge in an electric circuit component comes from the positively charged atoms of the conducting metal. The electrons move away from the plate that is to be positively charged (towards the positive pole of the voltage source with which the capacitor is being charged), and hence there is a net positive charge on the plate, since the ionized atoms" ...

If the capacitance is greater, I assume either the area of the capacitor plates is larger or the distance between the plates is smaller. Intuitively, how does the "larger areas" and the "smaller distance between the plates" affect the electrons" movement and the charge so that it manifests on charging velocity?

When the battery is first connected to the series of capacitors, it produces charge -q on the bottom plate of capacitor 3. That charge then repels negative charge from the top plate of capacitor 3 (leaving it with charge +q). The repelled negative charge moves to the bottom plate of capacitor 2 (giving it charge -q).
