

I want to know what the charging curve of a large capacitor might look like when connected to a voltage regulator output with current limiting, if that makes sense. The inrush current would likely trigger the current limit in reg for a spilt second, as if the capacitor was being fed from higher impedance source, as cap's current draw tapers off ...

Charging a Capacitor. When a battery is connected to a series resistor and capacitor, the initial current is high as the battery transports charge from one plate of the capacitor to the other. The charging current asymptotically approaches zero as the capacitor becomes charged up to the battery voltage.

provides a small trickle charge in the 100 mA range to slowly raise the pack cell voltage. Then the charger must charge at a low pre-charge current in the 100 mA to 800 mA range until the battery reaches 2.6-3.0 V typically (VBAT_LOWV). After those two stages, the CC and CV stages are the same for supercap charging as previously discussed.

Theory First we close the switch on the above circuit. As we saw in the previous tutorial, in a RC Discharging Circuit the time constant (t) is still equal to the value of 63%. Then for a RC discharging circuit that is initially fully charged, the voltage across the capacitor after one time constant, 1T, has dropped by 63% of its initial value which is 1 - 0.63 = 0.37 or 37% of its final value. Thus the time constant of ...
