

You cannot directly convert a battery's CCA or MCA rating to its amp hour rating. These ratings are measurements of the battery's ability to deliver a burst of power, not its capacity. However, you can estimate the amp hour rating of a battery by using a conversion chart or calculator that takes into account the battery's CCA or MCA rating, its voltage, and its ...

The higher the power, the quicker the rate at which a battery can do work--this relationship shows how voltage and current are both important for working out what a battery is suitable for. Capacity = the power of the battery as a function of time, which is used to describe the length of time a battery will be able to power a device for.

If, say you were to power the 12v Surface taking 2.58 amps, via a converter, powered by a 6v battery, then with a 100% efficient conversion, $2.58 \times 2 = 5.16A$ would be drawn from the 6v battery. I hope that clears things up.

The connections shown convert this switch-mode voltage regulator to a general-purpose current source. First, apply 5V to V+. Because the chip expects 12V of feedback at that terminal, it assumes a loss of regulation and shifts control to the current loop.

1700ma is 1.7-Amps, which equates to ~15-Watts, a single 9-Volt Battery can not produce 1.7-Amps on its best day. That's a Big-Fat Power-Supply, and You have a "Power-Hungry-Device", Battery

Figure 5: Inductor Current Waveform Rated Current (I DC, I RMS) The rated current refers to the DC current required to increase the inductor's temperature by a specified amount. The temperature rise (DT) is not a standard value, though it is usually between 20K

Meanwhile, some research focused on optimized control strategies of WT. A control strategy is presented in [23] to increase the DC voltage level during HVRT.[24] explained that if the GSC could inject certain amount of reactive current that matches the degree of the grid overvoltage, the voltage rise in the DC link caused by grid overvoltage would be alleviated.
