Familiarity with the capacitor and its charges would help one to clearly understand the principle of energy conservation and the energy storage in a capacitor. Energy is stored in a capacitor because of the purpose of transferring the charges onto a conductor against the force of repulsion that is acting on the already existing charges on it.

Secondly: When deriving the equation for energy stored in a capacitor you can work out the work done to move charge from one side plate to the other. But in the act of removing charge from one plate, you will change the potential between the plates, so why can we assume that the potential is constant when moving this charge from one plate to another.

According to this equation, the energy held by a capacitor is proportional to both its capacitance and the voltage's square. This makes obvious sense given that the capacitance of the capacitor, which determines the amount of charge it can store, and the voltage, which drives the accumulation of charge, are both related to the energy stored in the capacitor.

In electrical engineering, a capacitor is a device that stores electrical energy by accumulating electric charges on two closely spaced surfaces that are insulated from each other. The capacitor was originally known as the condenser, [1] a term still encountered in a few compound names, such as the condenser microphone..

Energy Stored in a Capacitor Work has to be done to transfer charges onto a conductor, against the force of repulsion from the already existing charges on it. This work is stored as a potential energy of the electric field of the conductor. Suppose a conductor of capacity C is at a potential V_0 and let q_0 be the charge on the conductor at this instant.

We can see from the equation for capacitance that the units of capacitance are C/V , which are called farads (F) after the nineteenth-century English physicist Michael Faraday. The equation $C = Q / V$ makes sense: A parallel-plate capacitor (like the one shown in Figure 18.28) the size of a football field could hold a lot of charge without requiring too much work per unit charge ...
