The capacitor voltage dividers use the capacitive reactance value of a capacitor to determine the actual voltage drop. They can only be used on frequency-driven supplies and they do not work as DC voltage dividers. This is mainly because the capacitors block DC and allows no current to flow. Presuming the capacitors have a similar charge, you can calculate the voltage from their capacitance values. Given that the $1\ \mu\text{F}$ capacitor value is half the $2\ \mu\text{F}$ capacitor value, the voltage of the first capacitor will be twice that of the second. Hence, the $1\ \mu\text{F}$ capacitor voltage will be 10 volts, and the $2\ \mu\text{F}$ capacitor voltage will be 5 volts.

In series combination, the same electrical current flows through each capacitor and the applied voltage V is divided across each capacitor. Due to external applied voltage each of the capacitors acquires an identical charge Q . The sum of the capacitor voltages must equal the source voltage (Kirchhoff's voltage law) $V = V_1 + V_2 + V_3$

This type of capacitor cannot be connected across an alternating current source, because half of the time, ac voltage would have the wrong polarity, as an alternating current reverses its polarity (see Alternating-Current Circuits on alternating-current circuits). Voltage. A capacitor will have a marked voltage indicating its acceptable peak voltage, not its operational voltage. Therefore, you can select a capacitor with a voltage rating at or above the original capacitor. If you're using a 370 volt capacitor, a 370 or 440 volt one will work, though the 440 volt unit will actually last longer.
