The light absorption mechanism is key to how solar cells work. When sunlight hits a solar cell, it starts various photon-electron interactions important for making energy. These interactions happen when photons, or light particles, hit electrons in the cell. This gives electrons the push they need to break free from atoms.

The theory of solar cells explains the process by which light energy in photons is converted into electric current when the photons strike a suitable semiconductor device. The theoretical studies are of practical use because they predict the fundamental limits of a solar cell, and give guidance on the phenomena that contribute to losses and solar cell efficiency.

3.2.1 Absorption and Energy Conversion of a Photon. When light illuminates a solar cell, the semiconductor material absorbs photons; thereby, pairs of free electrons and holes are created (see Fig. 3.1).
