We define the reactive power to be positive when it is absorbed (as in a lagging power factor circuit).. a. Pure capacitance element - For a pure capacitance element, $P=0$ and I leads V by 90° ; so that complex power is: $S = jQ = (V \angle 0^\circ)(I \angle 90^\circ)$; $S = V \angle 0^\circ I \angle -90^\circ$; $S = -jV \angle 0^\circ I$. Thus the capacitance element generates reactive power.

Since capacitors have a leading power factor, and reactive power is not a constant power, designing a capacitor bank must consider different reactive power needs. For example, the configuration for a 5-stage capacitor bank with a 170 KVAR maximum reactive power rating could be 1:1:1:1:1, meaning 5×34 KVAR or 1:2:2:4:8 with 1 as 10 KVAR.
