Once the switch is open, the applied voltage is soaked up by the capacitor and avoids damaging the contacts, preventing an arc from occurring, thus prolonging the use of the switch. Then when the switch closes again, the charged capacitor begins to discharge and the resistor current limits the inrush current.

⌘ If the capacitor reads as having fewer than 10 volts, you don't need to discharge it. If the capacitor reads anywhere between 10 and 99 volts, discharge it with a screwdriver. If the capacitor reads in the hundreds of volts, the safest ...
