The frequency of the signal is not a property of the coil alone, but of a resonant circuit which includes both the coil and a capacitor. You question is thus about tuning the resonant frequency. This may be done by varying the value of either the capacitor or the coil. Usually, varying the capacitance is easier.

Key learnings: Capacitor Definition: A capacitor is defined as a device that stores electric charge in an electric field and releases it when needed.; How to Test a Capacitor: To test a capacitor, you need to disconnect it, discharge it, and use a multimeter, resistance, or voltmeter to check its condition.; Multimeter Testing: Involves ...

Indicating that this particular capacitor is "good" up to around 0.1 MHz. Up to what frequency a capacitor is "good" depends on many things, it's value, the way it is constructed. What type of capacitor it is. Find a datasheet for a 10 pF capacitor and you will notice that it will still be "good" at a much higher frequency.

1. Model of capacitor under test. This model ignores lead inductance. Suppose that CUT is connected to a sine wave generator with frequency Fg and internal resistance rg, as shown in Fig. 2:

The output current is small for all frequencies except those very near the frequency \$omega_0\$, which is the resonant frequency of the cavity. resonance frequency of the NFC tag antenna is the frequency that results in a dip. Change the value of Ctune1 and Ctune2 to make it resonate on 13.56 MHz: o If the resonant frequency is lower than 13.56 MHz, the value of Ctune1 and Ctune2 should be decreased. o If the resonant frequency is higher than 13.56 MHz, the value of Ctune1 ...

resonant frequencies are measured by adjusting the signal generator until the peak reading is recorded on the millivolt meter. For each resonant frequency, the 3 dB bandwidth is determined by ...

Anyway Ott"s point was that this idea does not really work in practice because the large inductance that limits the big capacitor"s frequency response is still there, and in fact it ends up screwing up the smaller capacitor"s frequency response too -- the different frequency responses of the individual caps do not simply subtract from each ...

piece of Capacitor A meets the requirement, it occupies more space and costs more than other smaller capacitors. The question is which capacitor or capacitors should be added. The self-resonant frequency occurs at the resonant frequency of the ideal cap and series inductor (which form a tank circuit with near zero impedance at resonance). Once you go above resonance frequency, the series inductor dominates the impedance of the component, and the capacitor impedance is so low as to be negligible.

The impedance of a capacitor is the minimum point of its self-resonant frequency. This may be a smaller value than that of the ideal capacitor at this frequency. If the frequency of the noise is fixed, it is possible to obtain a significant noise reduction effect, as long as the self-resonant frequency can be adjusted to match the noise.
