

Lithium-ion battery compression

Separators exhibit harsh mechanical degradation as encounter various compression conditions within lithium-ion batteries (LIBs), deteriorating ion migration and cell performance directly.

As a result, existing lithium ion cells and battery packs are typically held under compression to maintain their overall dimensions during use [7, 8]. The volume growth in advanced anode alternatives such as Sn 258% and Si 311% has severely complicated their development and typically restricts their limits of practical lithiation.

A lithium-ion or Li-ion battery is a type of rechargeable battery that uses the reversible intercalation of Li + ions into electronically conducting solids to store energy. In comparison with other commercial rechargeable batteries, Li-ion batteries are characterized by higher specific energy, higher energy density, higher energy efficiency, a longer cycle life, and a longer ...

Rechargeable lithium-ion batteries (LIBs) stand out from numerous energy-storage equipment and become the current mainstay for electric vehicles and portable electronic devices due to the high energy density, long cycle life, high safety, and no memory effect [[1], [2], [3], [4]]. LIBs are chiefly constituted by the anode, cathode, separator, and electrolyte.

Understanding the mechanism of mechanical deformation/stress-induced electrical failure of lithium-ion batteries (LIBs) is important in crash-safety design of power LIBs.

The effects of a localized compression of a lithium-ion battery were investigated with a combination of experimental and modeling approaches. First, an axisymmetric p3D cell model was parameterized on the basis of a 2.1 Ah Kokam SLPB 356495 pouch cell and validated using experimental data. This electrochemical model was then complemented by a ...
