RC Circuits 6. The charge on a  $C = 0.4\text{F}$  capacitor is measured as a function of time in a physics lab and produces the following graph. The capacitor is part of a simple circuit having only a battery, a capacitor, and a resistor in series. The capacitor starts uncharged and at  $t=0\text{s}$ , the battery is plugged in and the capacitor charges.

Example: Suppose you have two identical  $1000\mu\text{f}$  capacitors, and connect them in series to double the voltage rating and halve the total capacitance. Let's also assume they are rated for  $100\text{ vdc}$  (working voltage) and  $125\text{v}$  maximum surge. Solve the equation, using  $V_m = 125$ , and  $V_b = 200$ .. Solution:  $R = (2 \times 125 - 200) / (0.0015 \times 1000 \times 200) = 50/300 = 0.167\text{ M} = \dots$

When you connect capacitors in series, any variance in values causes each one to charge at a different rate and to a different voltage. The variance can be quite large for ...

You can put capacitors in series, but that rarely works out better than getting the right cap in the first place. As Steven said, two of the same caps in series have double the voltage rating but half the capacitance. You also have to be careful that the DC level of the node between the caps is at about  $1/2$  the voltage.

Capacitors in Series and in Parallel. Multiple capacitors placed in series and/or parallel do not behave in the same manner as resistors. Placing capacitors in parallel increases overall plate area, and thus increases capacitance, as indicated by Equation ref{8.4}. Therefore capacitors in parallel add in value, behaving like resistors in series.
