PV voltage corresponds to open-circuit voltage ($N_{ser} \cdot V_{oc} = 5 \cdot 64.2 = 321$ V, see V_{mean} trace on PV scope). The three-level bridge operates as a diode rectifier and DC link capacitors are charged above 500 V (see V_{mean} trace on VSC scope). At $t=0.05$ sec, Boost and VSC converters are de-blocked. DC link voltage is regulated at $V_{dc}=500$ V.

A solar charge controller works by disconnecting the supply from the PV panels when the batteries are fully charged. But for some full-time liveaboards in sunny climates that can be considered a waste, when the excess power could be put to good use - heating water, say.

The and characteristics curve of the solar cell is shown in Fig. 2 [].The curve in this figure indicates that the operating point of the PV does not remain at a stable point; it actually varies from zero to open-circuit voltage.
