A superconductor is a material that has absolutely no electrical resistance (0 O) and interesting interactions with magnetic fields cause of this, it can transmit electricity without producing any waste heat. Dr Dias added that room temperature superconductors "can definitely change the world as we know it". In the US, electrical grids lose more than 5% of their energy through the process of transmission.

A large portion of the scientific community and public have turned against LK99. A room temperature superconductor is VERY hard work. The original cuprate superconductors had difficult replication until the YCBO formulation was discovered. The original LK99 only had partial levitation as shown here.

High Temperature Superconductors (referred to also as HTS or high-T c superconductors) have found demonstrated application in a vast variety of applications due to its high power density and high ...

The power grid does not get smarter to use solar, it gets dumber, delivering power during the day just to get rid of extra production. ... We already have liquid nitrogen temperature superconductors and that did not remove the need for helium cooled magnets because it did not have a very high critical field and, as a ceramic, it is really hard ...

Today, the highest temperature for a superconductor at ambient pressure is -225 degrees Fahrenheit--still cold, but nowhere near absolute zero. ... This Solar Coating Could One Day Power Your Phone.
