The final electrolytic capacitor type is the niobium oxide electrolytic. Developed during a tantalum shortage, the niobium electrolytic capacitor replaces tantalum with niobium and niobium pentoxide as the electrolyte. Due to its higher dielectric constant, it offers smaller package size per unit capacitance.

While tantalum capacitors are a subset of electrolytic capacitors, they differ in terms of construction, materials used, and performance characteristics.

The wet electrolytic tantalum capacitor was the first tantalum capacitor. It is in reality two electrochemical capacitors in series. It consists of a porous sintered tantalum anode, upon which has been grown a thin film of tantalum oxide (Ta_2O_5) which becomes the dielectric. The secondary capacitor plate is a combination of three materials.
