This article presents the basic theory on how a silicon-based PV cell converts sunlight into electricity. Silicon material and sunlight properties are reviewed with emphasis on the amount of energy that is needed to free valence electrons (i.e., bandgap) and energy

Photovoltaics is the process of converting sunlight directly into electricity using solar cells. Today it is a rapidly growing and increasingly important renewable alternative to conventional fossil fuel electricity generation, but compared to other electricity generating technologies, it is a relative newcomer, with the first practical photovoltaic devices demonstrated in the 1950s.

Some of the basic principles of photovoltaics are reviewed, especially concerning estimates of theoretical efficiency limits, improved photon utilization, contact optimization, and opportunities and technical problems arising for thin-film solar cells. Therefore, the explanation of semiconductor characteristics and the physical principles of photovoltaics should be based upon crystalline semiconductors, and in particular crystalline silicon. The chapter talks about the so-called Auger recombination.

At its core, PV relies on the principle of the photovoltaic effect, where certain materials generate an electric current when exposed to sunlight.

When light shines on a photovoltaic (PV) cell - also called a solar cell - that light may be reflected, absorbed, or pass right through the cell. The PV cell is composed of semiconductor material; the "semi" means that it can conduct electricity better than an insulator ...
