The ejected electrolyte may ignite surrounding combustible materials, causing further damage. The 50 % SOC battery demonstrates better thermal stability, with two flame jets during TR, a higher TR trigger temperature, and a more complete electrolyte reaction, leading to a higher peak TR temperature.

The broader application of lithium-ion batteries (LIBs) is constrained by safety concerns arising from thermal runaway (TR). Accurate prediction of TR is essential to comprehend its underlying mechanisms, expedite battery design, and enhance safety protocols, thereby significantly promoting the safer use of LIBs.

unmitigated, this overpressure can result in an explosion and severe damage to the battery and surrounding equipment or people. An explosion scenario can be even more severe for a large battery pack, where the heat generated by one failed cells can heat up neighboring cells and lead to a thermal cascade throughout the battery pack.
