Basically you need to choose one which will switch in the super capacitor when power is lost from the power adaptor. In normal operation after the capacitor has been charged it will just sit there being topped up every so often until needed. When the power is lost from the input the super capacitor switches in and delivers power to the load.

For example, a lead-acid battery charges up to a maximum of 13.8V and is considered dead (can't provide current anymore) when it's 11.4V. If you are using a capacitor to power something, then you must treat it similarly: It doesn't matter if your capacitor is truly dead when it's 0V if whatever you're powering requires at least 3V. \$endgroup\$

@Yehosef note that disabling write caching in the OS will not fix the fact that your drive corrupts data on power loss. For the sake of higher speed and durability consumer grade SSDs may not write data to non-volatile memory when you write to a file, and unfortunately there's no hardware mechanism for the drive to take the data from the volatile cache to non ...

The car will have a second ACC power line that has power throughout cranking, but it can be hard to find on the car's electrical wiring diagram. I take power off battery and added a switch/MCU timer to keep power-on to my accessories despite starting the car. You always need a fuse for the electronics and wires. 3A to 5A is good.

One of the first components to suffer this fate is the capacitor. It's one of the most commonly cited PCB repairs out there. Like any PCB component, a capacitor does its part to manage the electrical distribution throughout the PCB, helping the device function smoothly. Many capacitors store electrical charge through an electrolyte paste.

As a general rule, a generator will stop producing power if there is a tripped breaker, a bad outlet, the alternator loses its residual magnetism, the brushes are worn down, a defective ...
